

# C++ Primer I

CMSC 202

---

---

---

---

---

---

---

---

## Topics Covered

- Our first “Hello world” program
- Basic program structure
- main()
- Variables, identifiers, types
- Expressions, statements
- Operators, precedence, associativity
- Comments
- C-strings, C++ *string* class
- Simple I/O: cin, cout, cerr

2

---

---

---

---

---

---

---

---

## A Sample C++ Program

Display 1.1 A Sample C++ Program

```
1 #include <iostream>
2 using namespace std;
3 int main( )
4 {
5     int numberOfLanguages;
6     cout << "Hello reader.\n"
7         << "Welcome to C++.\n";
8     cout << "How many programming languages have you used? ";
9     cin >> numberOfLanguages;
10    if (numberOfLanguages < 1)
11        cout << "Read the preface. You may prefer\n"
12            << "a more elementary book by the same author.\n";
13    else
14        cout << "Enjoy the book.\n";
15    return 0;
16 }
```

---

---

---

---

---

---

---

---

## Using the C Compiler at UMBC

- Invoking the compiler is system dependent.
  - At UMBC, we have two C compilers available, `cc` and `gcc`.
  - For this class, we will use the `gcc` compiler as it is the compiler available on the Linux system.

4

---

---

---

---

---

---

---

---

## Invoking the gcc Compiler

At the prompt, type

```
g++ -Wall program.cpp -o program.out
```

where `program.cpp` is the C++ program source file (the compiler also accepts “.cc” as a file extension for C++ source)

- `-Wall` is an option to turn on all compiler **warnings** (best for new programmers).

5

---

---

---

---

---

---

---

---

## The Result : a.out

- If there are no errors in `program.cpp`, this command produces an **executable file**, which is one that can be executed (run).
- If you do not use the “-o” option, the compiler names the executable file `a.out`.
- To execute the program, at the prompt, type  
`./program.out`
- Although we call this process “compiling a program,” what actually happens is more complicated.

6

---

---

---

---

---

---

---

---

## UNIX Programming Tools

- We will be using the “make” system to automate what was shown in the previous few slides
- This will be discussed in lab

---

---

---

---

---

---

---

---

## Variable Declaration

- Syntax: `<type> <legal identifier>;`
- Examples:

```
int sum;  
float average;  
double grade = 98;
```

Semicolon required!

- Must be declared before being used
- May appear in various places and contexts (described later)
- Must be declared of a given type (e.g. int, float, char, etc.)

---

---

---

---

---

---

---

---

## Variable Declarations (con't)

When we declare a variable, we tell C++:

When and where to set aside memory space for the variable

How much memory to set aside

How to interpret the contents of that memory: the specified data **type**

What name we will be referring to that location by: its **identifier**

---

---

---

---

---

---

---

---

## Identifiers

Identifier naming rules apply to all variables, methods, class names, enumerations, etc.:

Typically consist of letters, digits, and underscores ('\_')

Must not start with a digit

Can be of any length

Are case-sensitive:

`Rate`, `rate`, and `RATE` are the names of three different variables.

Cannot be a keyword, or other reserved

10

---

---

---

---

---

---

---

---

## Naming Conventions

Naming *conventions* are additional rules that restrict the names of variables to improve consistency and readability

Most places of work and education have a set of naming conventions

These are not language or compiler enforced

We have our own CMSC 202 standards, given in detail on the course website, to be used on all projects

11

---

---

---

---

---

---

---

---

## Naming Conventions in C++

Variables:

Start with a lowercase letter

Indicate "word" boundaries with an uppercase letter

Restrict the remaining characters to digits and lowercase letters

`topSpeed` `bankRate1` `timeOfArrival`

Classes and functions

Start with an uppercase letter

Otherwise, adhere to the rules above

`FirstProgram` `MyClass` `BankAccount`

12

---

---

---

---

---

---

---

---

## Naming Conventions in C++

Class members:

Must have a "m\_" prefix

Then start with a lowercase letter

Rest of the rules the same as for variables

`m_name` `m_dailyRate`

Other rules as given on class web site

13

---

---

---

---

---

---

---

---

## Data Types: Display 1.2 Simple Types (1 of 2)

Display 1.2 Simple Types

TYPE NAME	MEMORY USED	SIZE RANGE	PRECISION
short (also called short int)	2 bytes	-32,768 to 32,767	Not applicable
int	4 bytes	-2,147,483,648 to 2,147,483,647	Not applicable
long (also called long int)	4 bytes	-2,147,483,648 to 2,147,483,647	Not applicable
float	4 bytes	approximately $10^{-38}$ to $10^{38}$	7 digits
double	8 bytes	approximately $10^{-308}$ to $10^{308}$	15 digits

Copyright © 2012 Pearson Addison-Wesley. All rights reserved.

1-14

---

---

---

---

---

---

---

---

## Data Types: Display 1.2 Simple Types (2 of 2)

long double	10 bytes	approximately $10^{-4932}$ to $10^{4932}$	19 digits
char	1 byte	All ASCII characters (Can also be used as an integer type, although we do not recommend doing so.)	Not applicable
bool	1 byte	true, false	Not applicable

The values listed here are only sample values to give you a general idea of how the types differ. The values for any of these entries may be different on your system. Precision refers to the number of meaningful digits, including digits in front of the decimal point. The ranges for the types float, double, and long double are the ranges for positive numbers. Negative numbers have a similar range, but with a negative sign in front of each number.

Copyright © 2012 Pearson Addison-Wesley. All rights reserved.

1-15

---

---

---

---

---

---

---

---

## Assigning Data

- Initializing data in declaration statement
  - Results "undefined" if you don't!
    - `int myValue = 0;`
- Assigning data during execution
  - Lvalues (left-side) & Rvalues (right-side)
    - Lvalues must be variables
    - Rvalues can be any expression
    - Example:  
`distance = rate * time;`  
Lvalue: "distance"  
Rvalue: "rate \* time"

---

---

---

---

---

---

---

---

## Data Assignment Rules

- Compatibility of Data Assignments
  - Type mismatches
    - General Rule: Cannot place value of one type into variable of another type
  - `intVar = 2.99; // 2 is assigned to intVar!`
    - Only integer part "fits", so that's all that goes
    - Called "implicit" or "automatic type conversion"
  - Literals
    - 2, 5.75, "z", "Hello World"
    - Considered "constants": can't change in program

---

---

---

---

---

---

---

---

## Display 1.3 Some Escape Sequences (1 of 2)

Display 1.3 Some Escape Sequences

SEQUENCE	MEANING
<code>\n</code>	New line
<code>\r</code>	Carriage return (Positions the cursor at the start of the current line. You are not likely to use this very much.)
<code>\t</code>	(Horizontal) Tab (Advances the cursor to the next tab stop.)
<code>\a</code>	Alert (Sounds the alert noise, typically a bell.)
<code>\\</code>	Backslash (Allows you to place a backslash in a quoted expression.)

---

---

---

---

---

---

---

---

### Display 1.3

#### Some Escape Sequences (2 of 2)

<code>\'</code>	Single quote (Mostly used to place a single quote inside single quotes.)
-----------------	--

<code>\"</code>	Double quote (Mostly used to place a double quote inside a quoted string.)
-----------------	--

The following are not as commonly used, but we include them for completeness:

<code>\v</code>	Vertical tab
-----------------	--------------

<code>\b</code>	Backspace
-----------------	-----------

<code>\f</code>	Form feed
-----------------	-----------

<code>\?</code>	Question mark
-----------------	---------------

---

---

---

---

---

---

---

---

## Constants

- You should not use literal constants directly in your code
  - It might seem obvious to you, but not so:
    - “limit = 52”: is this weeks per year... or cards in a deck?
- Instead, you should use named constants
  - Represent the constant with a meaningful name
  - Also allows you to change multiple instances in a central place

---

---

---

---

---

---

---

---

## Constants

- There are two ways to do this:
  - Old way: preprocessor definition:  
`#define WEEKS_PER_YEAR 52`  
This textually replaces the name with the value  
(Note: there is no “=“)
  - New, better way: constant variable:
    - Looks just like variable declaration, including type
    - Just add the keyword “const” to the declaration  
`const float PI = 52;`
    - Compiler enforces immutability

---

---

---

---

---

---

---

---

## Operators, Expressions

- Recall: most programming languages have a variety of *operators*: called unary, binary, and even ternary, depending on the number of operands (things they operate on)
- Usually represented by special symbolic characters: e.g., '+' for addition, '\*' for multiplication
- There are also relational operators, and Boolean operators

Copyright © 2012 Pearson Addison-Wesley. All rights reserved.

1-22

---

---

---

---

---

---

---

---

## Operators, Expressions

- Simple units of operands and operators combine into larger units, according to strict rules of *precedence* and *associativity*
- Each computable unit (both simple and larger aggregates) are called *expressions*

Copyright © 2012 Pearson Addison-Wesley. All rights reserved.

1-23

---

---

---

---

---

---

---

---

## Binary Operators

- What is a binary operator?
  - An operator that has two operands
    - <operand> <operator> <operand>
  - Arithmetic Operators
    - + - \* / %
  - Relational Operators
    - < > == <= >=
  - Logical Operators
    - && ||

24

---

---

---

---

---

---

---

---

## Relational Operators

- In C++, all relational operators evaluate to a boolean value of either **true** or **false**.

- `x = 5;`
  - `y = 6;`

- `x > y` will always evaluate to **false**.

- C++ has a ternary operator – the general form is:

- `(conditional expression) ? true case : false case ;`

- For example:

- `Cout << (( x > y ) ? "X is greater" : "Y is greater");`

25

---

---

---

---

---

---

---

---

## Unary Operators

- Unary operators only have one operand.

- `! ++ --`

- `++` and `--` are the **increment** and **decrement** operators
    - `x++` a **post-increment** (postfix) operation
    - `++x` a **pre-increment** (prefix) operation

- What is the difference between these segments?

- `x = 5;`
  - `cout << "x's value is" << x++;`
    - `x = 5;`
    - `cout << "x's value is" << ++x;`

26

---

---

---

---

---

---

---

---

## Precedence, Associativity

- Order of operator application to operands:

- Postfix operators: `++ --` (right to left)
- Unary operators: `+ - ++ -- !` (right to left)
- `* / %` (left to right)
- `+ -` (left to right)
- `< > <= >=`
- `== !=`
- `&&`
- `||`
- `? :`
- Assignment operator: `=` (right to left)

27

---

---

---

---

---

---

---

---

## Arithmetic Precision

- Precision of Calculations
  - VERY important consideration!
    - Expressions in C++ might not evaluate as you'd "expect"!
  - "Highest-order operand" determines type of arithmetic "precision" performed
  - Common pitfall!

---

---

---

---

---

---

---

---

## Arithmetic Precision Examples

- Examples:
  - $17 / 5$  evaluates to 3 in C++!
    - Both operands are integers
    - Integer division is performed!
  - $17.0 / 5$  equals 3.4 in C++!
    - Highest-order operand is "double type"
    - Double "precision" division is performed!
  - `int intVar1 =1, intVar2=2;`  
`intVar1 / intVar2;`
    - Performs integer division!
    - Result: 0!

---

---

---

---

---

---

---

---

## Individual Arithmetic Precision

- Calculations done "one-by-one"
  - $1 / 2 / 3.0 / 4$  performs 3 separate divisions.
    - First  $\rightarrow 1 / 2$  equals 0
    - Then  $\rightarrow 0 / 3.0$  equals 0.0
    - Then  $\rightarrow 0.0 / 4$  equals 0.0!
- So not necessarily sufficient to change just "one operand" in a large expression
  - Must keep in mind all individual calculations that will be performed during evaluation!

---

---

---

---

---

---

---

---

## Type Casting

- Two types
  - Implicit—also called "Automatic"
    - Done FOR you, automatically  
17 / 5.5  
This expression causes an "implicit type cast" to take place, casting the 17 → 17.0
  - Explicit type conversion
    - Programmer specifies conversion with cast operator  
(double)17 / 5.5  
Same expression as above, using explicit cast  
(double)myInt / myDouble  
More typical use; cast operator on variable

---

---

---

---

---

---

---

---

## Type Casting

- Casting for Variables
  - Can add ".0" to literals to force precision arithmetic, but what about variables?
    - We can't use "myInt.0"!
  - static\_cast<double>intVar
  - Explicitly "casts" or "converts" intVar to double type
    - Result of conversion is then used
    - Example expression:  
doubleVar = static\_cast<double>intVar1 / intVar2;
      - Casting forces double-precision division to take place among two integer variables!

---

---

---

---

---

---

---

---

## Shorthand Operators

- Increment & Decrement Operators
  - Just short-hand notation
  - Increment operator, ++  
intVar++; is equivalent to  
intVar = intVar + 1;
  - Decrement operator, --  
intVar--; is equivalent to  
intVar = intVar - 1;

---

---

---

---

---

---

---

---

## Shorthand Operators: Two Options

- Post-Increment  
`intVar++`
  - Uses current value of variable, THEN increments it
- Pre-Increment  
`++intVar`
  - Increments variable first, THEN uses new value
- "Use" is defined as whatever "context" variable is currently in
- No difference if "alone" in statement:  
`intVar++`; and `++intVar`; → identical result

---

---

---

---

---

---

---

---

## Post-Increment in Action

- Post-Increment in Expressions:  

```
int    n = 2,  
      valueProduced;  
valueProduced = 2 * (n++);  
cout << valueProduced << endl;  
cout << n << endl;
```

  - This code segment produces the output:  
4  
3
  - Since post-increment was used

---

---

---

---

---

---

---

---

## Pre-Increment in Action

- Now using Pre-increment:  

```
int    n = 2,  
      valueProduced;  
valueProduced = 2 * (++n);  
cout << valueProduced << endl;  
cout << n << endl;
```

  - This code segment produces the output:  
6  
3
  - Because pre-increment was used

---

---

---

---

---

---

---

---

## Assigning Data: Shorthand Notations

- Display, page 14

EXAMPLE	EQUIVALENT TO
<code>count += 2;</code>	<code>count = count + 2;</code>
<code>total -= discount;</code>	<code>total = total - discount;</code>
<code>bonus *= 2;</code>	<code>bonus = bonus * 2;</code>
<code>time /= rushFactor;</code>	<code>time = time/rushFactor;</code>
<code>change %= 100;</code>	<code>change = change % 100;</code>
<code>amount *= cnt1 + cnt2;</code>	<code>amount = amount * (cnt1 + cnt2);</code>

---

---

---

---

---

---

---

---

## Commenting Programs

- A **comment** is descriptive text used to help a *reader* of the program understand its content.
- C++ supports two different styles of comments
- Style 1: multi-line comments:
  - Comment begins with the characters `/*` and end with the characters `*/`
  - These are called **comment delimiters**
  - As the name implies, these comments can span multiple lines

---

---

---

---

---

---

---

---

## Commenting Programs

- Style 2: single-line comments:
  - Comment begins anywhere in a line with a `/**` (a double forward-slash)
  - Everything from the `/**` to the end of the line is ignored as a comment
- Comments (especially program header comments) are critical to good programming, and will be stressed in class projects
- Look at the class web page for the required contents of our header comment.

---

---

---

---

---

---

---

---

## Comment Examples

- End of line comment:

```
vol = x * y * z; // compute the volume
```

- Multi-line comment:

```
/*  
 * sort the array using  
 * selection sort  
 */
```

40

---

---

---

---

---

---

---

---

## Tricky Comments

- What will this do?

```
/* Comments  
cout << "Hello";  
// */
```

- What about this?

```
// /* Comments  
cout << "Hello";  
*/
```

Copyright © 2012 Pearson Addison-Wesley. All rights reserved.

1-41

---

---

---

---

---

---

---

---

## C-strings

- C++ has two different kinds of “string of characters”:
  - the original C-string: array of characters
  - The object-oriented *string* class
- C-strings are terminated with a null character (`'\0'`)  
`char myString[80];`  
would declare a variable with enough space for a string with 79 usable characters, plus null

Copyright © 2012 Pearson Addison-Wesley. All rights reserved.

1-42

---

---

---

---

---

---

---

---

## C-strings

- You can initialize a C-string variable:  
`char myString[80] = "Hello world";`
  - This will set the first 11 characters as given, make the 12<sup>th</sup> character `'\0'`, and the rest unused for now

---

---

---

---

---

---

---

---

## String type

- C++ added a data type of "string" to store sequences of characters
  - Not a primitive data type; distinction will be made later
  - Must add `#include <string>` at the top of the program
  - The "+" operator on strings concatenates two strings together
  - `cin >> str` where `str` is a string only reads up to the first whitespace character

---

---

---

---

---

---

---

---

## String Equality

- In Python, you can use the simple "==" operator to compare two strings:  
if `name == "Fred"`:
- In C++, you can use "==" to compare two *string* class items, **but not C-strings!**
- To compare two C-strings, you have to use the function `strcmp()`; it is not syntactically incorrect to compare two C-strings with "==" , but it does not do what you expect...

---

---

---

---

---

---

---

---

## Console Input/Output

- I/O objects cin, cout, cerr
- Defined in the C++ library called <iostream>
- Must have these lines (called pre-processor directives) near start of file:
  - #include <iostream>  
using namespace std;
  - Tells C++ to use appropriate library so we can use the I/O objects cin, cout, cerr

---

---

---

---

---

---

---

---

---

---

## Console Output

- What can be outputted?
  - Any data can be outputted to display screen
    - Variables
    - Constants
    - Literals
    - Expressions (which can include all of above)
  - cout << numberOfGames << " games played.";  
2 values are outputted:  
"value" of variable numberOfGames,  
literal string " games played."
- Cascading: multiple values in one cout

---

---

---

---

---

---

---

---

---

---

## Separating Lines of Output

- New lines in output
  - Recall: "\n" is escape sequence for the char "newline"
- A second method: object endl
- Examples:

```
cout << "Hello World\n";
```

  - Sends string "Hello World" to display, & escape sequence "\n", skipping to next line

```
cout << "Hello World" << endl;
```

  - Same result as above

---

---

---

---

---

---

---

---

---

---

## Input/Output (1 of 2)

Display 1.5 Using cin and cout with a string (part 1 of 2)

```
1 //Program to demonstrate cin and cout with strings
2 #include <iostream>
3 #include <string> Needed to access the string class.
4 using namespace std;
5 int main()
6 {
7     string dogName;
8     int actualAge;
9     int humanAge;
10
11     cout << "How many years old is your dog?" << endl;
12     cin >> actualAge;
13     humanAge = actualAge * 7;
14
15     cout << "What is your dog's name?" << endl;
16     cin >> dogName;
17
18     cout << dogName << "'s age is approximately " <<
19         "equivalent to a " << humanAge << " year old human."
20         << endl;
21
22     return 0;
23 }
```

Copyright © 2012 Pearson Addison-Wesley. All rights reserved.

1-49

---

---

---

---

---

---

---

---

---

---

## Input/Output (2 of 2)

Display 1.5 Using cin and cout with a string (part 2 of 2)

Sample Dialogue 1

```
How many years old is your dog?
5
What is your dog's name?
Rex
Rex's age is approximately equivalent to a 35 year old human.
```

Sample Dialogue 2

```
How many years old is your dog?
10
What is your dog's name?
Mr. Bojangle "Bojangle" is not read into dogName because cin stops input at the space.
Mr.'s age is approximately equivalent to a 70 year old human.
```

Copyright © 2012 Pearson Addison-Wesley. All rights reserved.

1-50

---

---

---

---

---

---

---

---

---

---

## Formatting Output

- Formatting numeric values for output
  - Values may not display as you'd expect!  
cout << "The price is \$" << price << endl;
  - If price (declared double) has value 78.5, you might get:
    - The price is \$78.500000 or:
    - The price is \$78.5
- We must explicitly tell C++ how to output numbers in our programs!

Copyright © 2012 Pearson Addison-Wesley. All rights reserved.

1-51

---

---

---

---

---

---

---

---

---

---

## Formatting Numbers

- "Magic Formula" to force decimal sizes:  
`cout.setf(ios::fixed);`  
`cout.setf(ios::showpoint);`  
`cout.precision(2);`
- These stmts force all future cout'ed values:
  - To have exactly two digits after the decimal place
  - Example:  
`cout << "The price is $" << price << endl;`
    - Now results in the following:  
The price is \$78.50
- Can modify precision "as you go" as well!

---

---

---

---

---

---

---

---

## Error Output

- Output with cerr
  - cerr works same as cout
  - Provides mechanism for distinguishing between regular output and error output
- Re-direct output streams
  - Most systems allow cout and cerr to be "redirected" to other devices
    - e.g., line printer, output file, error console, etc.

---

---

---

---

---

---

---

---

## Input Using cin

- cin for input, cout for output
- Differences:
  - ">>" (extraction operator) points opposite
    - Think of it as "pointing toward where the data goes"
  - Object name "cin" used instead of "cout"
  - No literals allowed for cin
    - Must input "to a variable"
- `cin >> num;`
  - Waits on-screen for keyboard entry
  - Value entered at keyboard is "assigned" to num

---

---

---

---

---

---

---

---

## Prompting for Input: cin and cout

- Always "prompt" user for input  
cout << "Enter number of dragons: ";  
cin >> numOfDragons;
  - Note no "\n" in cout. Prompt "waits" on same line for keyboard input as follows:  
  
Enter number of dragons: \_\_\_\_
- Underscore above denotes where keyboard entry is made
- Every cin should have cout prompt
  - Maximizes user-friendly input/output

---

---

---

---

---

---

---

---

## Reading from the Console

```
int n1, n2;  
cout << "Enter 2 numbers to sum: ";  
cin >> n1 >> n2;  
cout << n1 << "+" << n2 << "=" << (n1 + n2);
```

- Let's assume the user has entered "128 10".
- The first "<<" reads the characters "128" leaving "10\n" in the input buffer.
- The second "<<" (same expression) reads the "10" and leaves the "\n" in the buffer. THIS WILL BE IMPORTANT LATER.

---

---

---

---

---

---

---

---

## Libraries

- C++ Standard Libraries
- #include <Library\_Name>
  - Directive to "add" contents of library file to your program
  - Called "preprocessor directive"
    - Executes before compiler, and simply "copies" library file into your program file
- C++ has many libraries
  - Input/output, math, strings, etc.

## Namespaces

- Namespaces defined:
  - Collection of name definitions
- For now: interested in namespace "std"
  - Has all standard library definitions we need
- Examples:
  - `#include <iostream>`  
`using namespace std;`
    - Includes entire standard library of name definitions
  - `#include <iostream>using std::cin;`  
`using std::cout;`
    - Can specify just the objects we want
